Abstract

Generative AI has rapidly changed how students and educators work, prompting universities to reconsider their academic policies. Faculties have scrambled to implement policies on the ethical use of this new technology, leading to an inconsistent standard across universities in the Australasian region. Our goal was to study the breadth of these policies. To analyze them, categorize them and synthesize them into a new unified policy set, made accessible to all students and faculty at Australasian universities. We took the official policy documents of over a dozen universities and analyzed them. We categorised the policies for both students and educators. We then drew on these categorized policy areas to create our unified policy set and built a tool that allows users to understand it, with diagrams and examples. In the end, GenAI Policy Scanner is both a stepping stone and a tool for future researchers and educators to build on our research for a more structured, ethical, and transparent use of generative AI in higher education.

Introduction

1. Background and Context

Generative AI is disrupting the ways students learn, academics teach, and people imagine innovation. Universities now face new avenues for efficiency and creativity, which pose challenges for academic honesty and authorship. Each university is adopting its own regulations, which vary widely. While some policies are clear and functional, others are unclear, incomplete or not transparent to the public. This inconsistency makes it difficult for students and staff to know what is permitted and what is not, and it also demonstrates a lack of consensus about the role of AI in education.

2. Motivation

The motivation for this project came from this inconsistency. We aimed to understand exactly how universities are defining and regulating the use of AI and whether the scattered information could be brought together. As AI seeps into all areas of academic life, a standard set of transparent policies is increasingly important. By mapping, analysing and uniting these policies into a single reference point, we sought to fill this gap.

3. Proposed Solution

We created GenAI Policy Scanner, a web-based tool for gathering and comparing university AI policies across Australasia. We simplified the complexity of the documents by organising them into subcategories, making the policies easier to interpret and compare. We developed a single policy statement that spells out what is and is not allowed and clarifies how universities are managing AI in teaching, assessment, and research.

4. Key Contributions

- Developed a 4-level system to compare and categorise the various universities' AI policies.
- Created a unified approach to AI policy with real examples that both students and staff members could understand and easily apply to their specific situations.
- Created a web-based tool that allows users to easily interpret and assess their governance of using AI.

Methodology

Overview

This project aimed to address the inconsistency and fragmentation in how Australasian universities document generative artificial intelligence in education. While many institutions have developed their own policies and guidelines, these documents often vary widely in scope, delivery, and interpretation, and some even conflict with other universities' policies. To resolve this issue, our team, IT25, developed a singular, unified framework that consolidates the strengths of existing university policies into a single, presentable policy accessible via a website.

The methodology adopted for this project involved the collection, documentation, and analysis of GenAI-related policies from Australian and New Zealand universities listed in the ACDICT members list (ACDICT, n.d.). After the required data was collected and documented, an interactive website to present the unified policy was created. The website serves as a streamlined tool that could be used by educators and students from universities in the Australasia region seeking guidance on AI policy..

1. Data Collection

Policies and guidelines were collected from official university websites and repositories across Australia and New Zealand. The scope included all institutions listed under the Australasian Council of Deans of Information and Communications Technology (ACDICT, n.d.). Where possible, data collection was conducted through manual searches using consistent keywords (e.g., “AI policy,” “ChatGPT,” “academic integrity,” “assessment and AI use”). The collected data was documented inside a shared Excel file to allow centralised categorisation between group members.

2. Policy Analysis and Categorisation

After data collection, the team systematically analysed each policy to identify recurring themes, unique approaches, and inconsistencies. Policies were coded and categorised according to their focus areas, such as academic integrity, assessment design and evaluation, staff guidance, and teaching practices. A comparative analysis was then conducted to identify similarities and differences among universities' policies and guidelines. This step enabled the team to extract key insights and best practices that informed the structure of the unified framework.

3. Unified Policy Development

Based on the comparative findings, the team developed a consolidated GenAI policy framework that synthesised the most effective and ethically grounded elements from each institution's approach. This unified policy was structured into categories and subcategories reflecting key domains of academic activity, allowing users to locate relevant policies for their context easily. The framework was intentionally designed to be comprehensive yet adaptable, allowing it to be open to changes within the institution and generative artificial intelligence development.

4. Website Design and Implementation

To enhance accessibility and usability, the unified framework was presented through a dedicated web application. The website was designed with a clean and modern interface, allowing users to explore the policy structure intuitively. The design process prioritised:

- Navigation: Clear categorisation and subcategorisation for both students and educators.
- Accessibility: Simple language and layout suitable for all user types.
- Minimal empty space: the website is designed to ensure that all spaces are utilised to the fullest extent on the website, leaving no blank spaces. The website functions as both a repository and an interactive tool, enabling users to browse, compare, and interpret AI policies across educational domains.

Experimental Evaluation

1. Experimental Set-up

a. Scope & Source discovery

Our team set the scope to the complete ACDICT (2025) list of Australian universities and restricted sources to official and public data. Each university would be assigned to a specific scope, which would later be used in the category map. Only policies issued or updated within the past 24 months will be accepted, unless a newer document explicitly replaces them.

There are two main processes for source discovery: manual search and lightweight scraping. Each member involved in the manual search used a template, called a search log, to record where and how the team searched

for the data, the time, and the keywords/queries used. Maintaining a shared research logbook is expected to provide the entire team with an auditable record of raw data, analyses, and decisions (Schreier, Wilson & Resnik 2006). Moreover, the team could save time by preventing duplication and capturing the rationale for protocol changes (Schreier, Wilson & Resnik 2006). The scraping tool was designed to collect information at scale and faster. The collected data will then be transferred to a JSON file and later evaluated by a human to eliminate errors and use the relevant ones.

The feasibility of this discovery, both through manual search and through a scraping tool, is measured by coverage at least 95% of the selected universities with at least one official and updated policy.

b. Categorisation

The science of categorisation is essential to the project’s development, as it not only provides a comprehensive framework for GenAI policies but also enables comparisons and analysis. Categorisation is a ubiquitous process that appears in a variety of contexts. It refers to the process of grouping items/entities into socially shared categories (Vergne & Wry 2014), enabling an organised structure for how people perceive and shape cognitive thinking (Douglas 1986). In our GenAI Scanner project, categorisation was used to partition educational GenAI policies into groups such as Learning, Lab/Practical, Mathematical, Creative Design, Creative Thinking, Academic Writing, and Programming, thereby organising diverse GenAI policy statements into a common structure. This categorisation is expected to make different universities’ policies directly comparable, highlighting where guidance is strong or missing, and provide a clear basis for analysing gaps and inconsistencies in GenAI support for students.

A category was formed by reflecting on the actual experience at university, analysing raw information, collecting headings and statements from the institution’s handbook, guidelines and rules. Later, the findings would be compared to practical scenarios to determine whether the category could successfully capture the policies’ properties and nature, as well as the university’s intention.

c. Policy Recordkeeping

The research was measured and underwent a policy recordkeeping process. Recordkeeping is the evidence-based process of creating, capturing, and managing information to ensure authentic, usable information over time

(Grant 2017). Each policy would be treated as a record, and essential metadata would be captured, including title, author/university, and dates. The journal or so-called recording document was then signed by a member who researched the university for authenticity and logging purposes. The research is considered successful only if it includes a version control system. Having version control allows us to keep track of the current policy and compare it with older versions to analyse shifts in GenAI policy. Either internal changes or updates within the university's policy will be recorded in the journal. An effective policy journal will allow the team to identify the strengths and weaknesses in how universities design their policy frameworks. At the same time, on a broader scale, it can highlight trends in how educational policy has shifted in the AI area.

d. Taxonomy Design - category map

The core taxonomy that our group aims for is the category map. It is a tree diagram that splits categories into levels. FigmaJam was used to develop the category map, serving as the shared workplace and chart demonstrator. Level 1 - Domain: this is the top and broadest level of the map, highlighting the broad areas of the policy, such as Assessments and Learning for Students and Course Design and Grading for Educators. Level 2 - Category: The headline/title of the broad category. Level 3 - Sub-category: More specific policies that expand the definition and nature of the Level 2 category. Level 4 - Each level 3 category will be linked to a specific use case, providing a concise, representative policy that reflects the majority of universities in that category. By connecting the policy to the use case, it gives clear guidance for both students and educators, helps verify meaning, quickly identifies patterns, enhances understanding, and fosters shared knowledge, making the policy more relatable to users through day-to-day scenarios (Blaha et al. 2022).

The category map is a concept that we established for three purposes: (1) Foundation of the project. The category map is a shared language that every group member can follow and use to conduct research. (2) Putting the findings into an accurate category that can reflect the true nature of the policy. (3) Acting as a structured policy guideline and a UI schema that forms layers of categories, policies, summaries, and comparisons. A defined and comprehensive taxonomy is not only the final output of the project, but also showcases the finalised/unified policy framework that universities across Australasia can comply with and reference, and serves

as a bridge for effective communication, a foundation for research development, and a front-end framework. The following criteria will measure the taxonomy's success.

- A 0% category-overlap rate backed by a concise per category that critically and accurately represents the majority of the universities. Human check with a reviewing session supervisor.
- at least 98% completeness as the level 3 category is filled with detailed policy and specific use cases. Human check is the key factor to determine the success of this criterion

- at least 90% reviewers/beta-testers find the Level 3 policies and use cases easy to follow and relatable. Google Forms will be used as the bridge between the team and the reviewers. The demo will be shared among university students and peers.

e. Team Review and Finalisation

The objective of the team review is to carefully evaluate and identify errors and blind spots in the taxonomy. Our summaries and use cases must match the sources. The team was split into two groups for two rounds of inspection and checks. Each group would identify and flag potential errors, note necessary adjustments, and then compare the logs for internal discussion. The split was intended to ensure there would be no bias in the chosen target research and fairness in feedback. For this process, Google Docs and Google Spreadsheets were used for team collaboration, ensuring up-to-date findings and comprehensive records. The log documentation will be constantly updated on what has changed and the reason behind it. For the finalised outcome, the team expected to produce: (1) Taxonomy - A unified GenAI policy guideline for Australasia students and educators (2) Website Application - An interactive website In short, FigmaJam, Google Spreadsheets and Overleaf (Latex) were used to produce and showcase the category map. While the Website Application would be developed using HTML/CSS/JS under the React framework

2. Result and Analysis

The team developed two comprehensive category maps (Figure 1 and 2) to visually demonstrate how GenAI policies are organised and applied across different contexts. Each map showcases the core categories, which were used not only to evaluate appropriateness and consistency but also to identify areas where guideline implementation should be further developed.

Figure 1: Category map of educator GenAI Policy

Figure 2: Category map of student GenAI policy

Regarding the category maps, our team could expand and identify more specific policies within the broader categories. The creation of the category maps resulted from analysing and grouping GenAI policies into clearly defined use-case categories for both students and educators. Where complex policy documents were critically summarised and organised into a visual structure. Through this process, complex policy documents were distilled into a visual structure that highlights how guidance is distributed across different learning activities. The life-cycle of assessment implementation was utilised to capture how average students start and complete assignments. Multiple rounds of audit were

conducted to ensure that there would be no overlaps while maintaining the core properties of each category. While learning itself is very broad and overlaps if expanded further, assessments take a variety of forms across hundreds of courses and subjects. The team was able to narrow down, eliminate redundancy, and finalise a comprehensive map illustrating the foundation of educational assessment policies. Two availability tables highlighted the distribution of GenAI policy across 28 selected universities. The purpose of the tables is to tell which universities provide comprehensive coverage of GenAI governance. This allows the team to identify gaps and challenges, and to compare overall preparedness and consistency among institutions. Ultimately, these availability tables provide a clear and evidence-based picture of how universities are implementing integration for both students (Figure 3) and educators (Figure 4).

Legend: Available – N/A △ Partial/unclear

Figure 3: Availability table for student GenAI policy across 28 universities

The findings highlight major differences across universities in terms of policy assessment systems, scope, security, and availability. There are only five institutions that have a completed/partially completed GenAI guideline for students that aligns with the category map. The others either cover vaguely or have limited coverage. We confirmed that there is a lack of unified, foundational guidelines for universities to reference. While the University of Western Australia (2025) and Flinders University (2024, 2025 (a) (b)) use a tiered assessment

system to categorise their GenAI policies, Deakin University (2025, 2024 (a) (b)), one of the universities that lays the foundation for GenAI policy in higher education in Australia, takes a different approach to presenting its policies. The student’s GenAI policy availability map shows a clear trend of insufficient governance for Lab Assessment, Mathematical, Creative Design, and Creative Writing. The Learning, Academic Writing, and Programming categories provide greater coverage and more detailed policies

than the four categories mentioned. Across the educator GenAI policy availability tables, 0% of universities offer a comprehensive, fully articulated guideline for the three categories of Learning, Course Design, and Grading. Two scenarios can explain this: either the university has unclear or limited policies, or the policies were restricted to outsiders. The restricted access for policy reviewing will be discussed further in the Discussion.

Figure 4: Availability table for educator GenAI policy across 28 universities

The following table will summarise the key differences and similarities in GenAI policy governance across the 28 ACDICT universities.

Similarities	Differences
1. “Refer to the course coordinator for detailed information on the assessments”. Universities use this phrase to shift the GenAI controls to internal courses rather than having a general framework. 2. Most universities use government frameworks, such as the Australian Code for the Responsible Conduct of Research (2018) or the Australian Framework for Generative Artificial Intelligence (AI) in Schools (n.d.), or reference existing policies from other universities rather than designing a specific guideline. 3. AI-generated output is generally not allowed in any kind of gradeable assessments. Universities aim to increase students’ and educators’ responsibility and their own work. Students must demonstrate their understanding of learning and the completion of assignments, while human factors must remain the primary consideration in educators’ decision-making. 4. AI is encouraged in the learning process. GenAI must remain a tool that aids learning rather than the key factor of assignment-taking. Disclosure of AI	1. Different policy-assessment systems. While some universities effectively categorise their policies using tiered assessment, others only outline the rules vaguely, making it hard for students and educators to comply. 2. Availability. Access to the GenAI policies is restricted to a few universities, which will be mentioned later in the <i>Discussion</i>. 3. Level 3 categories show differences between universities. Each university has its own view on how to use AI in several contexts. 4. Detailed, use-case-specific rules (with examples) vs broad, high-level principles vs one-line mentions. 5. Allowed with conditions” vs “default ban unless approved” vs “silent/unspecified”. 6. Scope of the policy: Applied across the university, faculty-wide and course-wide.

A survey was sent to examine the effectiveness of the summarised combined with the specific scenario. From Figure 5, the results indicate that 298 out of 328 respondents (90.9%) found the summarised policies understandable in universal terms, while putting respondents in actual scenarios increases reliability.

Are the specific use cases described in the Level 3 category relatable and helpful in understanding?
328 responses

Figure 5: Results from earlier users about the feasibility and effectiveness of the use cases described in the Level 3 category

Discussion

The following section reflects on the outcomes of our project, beginning with the decisions and actions that worked well, then the challenges faced, and concluding with the practical applications of the unified policy guideline and the website application we developed.

1. Successful Strategies

In terms of project management, our team followed a decentralised approach, allowing members to choose tasks based on their individual strengths instead of assigning rigid roles. With eight members, this strategy proved effective across most aspects of our project: some focused entirely on research and policy development, while others concentrated on design and application development, according to their personal skill sets and preferences. Initially, this approach seemed counterintuitive; however, given the team's size and differing schedules and work styles, strictly dividing every task equally among all members would have caused delays, as the rest of the team would have had to wait until the last person finished their allocated section.

We held weekly in-person meetings in addition to workshops and supervisor meetings. Outside of meetings, we regularly communicated through our group chat, which helped us coordinate as the project progressed and requirements evolved. We also created and shared meeting summaries so absent members could stay informed, and our supervisor could stay on-track and build on top of previous feedback given.

The research component of our project, which spanned from the beginning of the project through to week 10, began with researching and creating policy summaries for all 28 ACDICT (2025) universities. This was followed by creating the taxonomy and policy categorisation spreadsheet, with rows representing our categories (tasks) and columns representing universities. This structure allowed us to map policies to specific tasks (technical writing etc.) and systematically compare them to create unified policies. Although the spreadsheet was time-intensive to build, it allowed us to easily and quickly create the final unified policies, which was one of our main deliverables.

We also adopted an iterative design process. Multiple team members independently produced different interface designs and taxonomies at first, which we then reviewed collectively, and continued refining and developing them as a group. This enabled us to gather multiple perspectives and ideas, as well as identify potential shortcomings, which improved the overall quality of our final solutions.

2. Challenges Faced

Challenges encountered during research

The primary challenge was the 12-week time constraint of our project. The extensive research required before drafting the unified policies created a bottleneck that slowed progress. Initially, we divided the 28 universities among members and started summarising their policies before designing the spreadsheet; an inefficient order. Had we built the spreadsheet first, our workflow would have been more streamlined, and we could have saved a significant amount of time. Furthermore, the time constraints also led our

supervisor to reduce the project scope, removing the comparison with overseas universities that had been part of the original plan.

Certain universities had also restricted public access to certain policy pages, especially educator policies and guidelines, likely for security reasons (Curtin University 2025, University of Tasmania 2025, University of South Australia 2025, Murdoch University 2025). Fortunately, most universities (eg. Central Queensland University, 2025, University of Newcastle 2025, University of Southern Queensland) still maintained publicly available policies that we could use for our analysis.

Since our taxonomy spanned into highly specific tasks (writing outlines for Technical writing, Summarising sources for research, Analysing results of lab experiments etc.), policies for nodes were difficult and sometimes impossible to locate. Following the supervisor’s guidance, we inferred the unified policies for these cases based on related or higher-level policies, combined with our own understanding of ethical generative AI usage, ensuring a logical and consistent guideline for all tasks.

Challenges encountered during development

After we completed developing our application, our supervisor requested that we deploy it publicly, at which point we started encountering several issues. Although the application ran smoothly in local tests, it produced routing and accessibility errors (related to environment compatibility) when deployed on our Hostinger shared hosting plan. After several days of debugging, we created a Dockerfile to eliminate environment inconsistencies. This solution resolved the issues and allowed successful deployment.

Representing the categorisation in an intuitive, accessible and user-friendly way also proved to be difficult. We experimented with several interfaces, beginning with a dropdown-style layout before switching to a flowchart-style visualisation. Based on supervisor feedback, we decided to include both in the final version to maximise usability.

Due to the web app starting development early with only one group member working on it, when it came time for the project to refocus on the app after the research was done, it was difficult for other group members to get up to speed on the web app in the final weeks of the project.

3. Practical Applications of our Project

The key benefit, as well as the purpose of our project, is providing a set of unified policies that both students and educators in Australasia can follow, in order to use AI ethically and responsibly, without compromising educational outcomes such as critical thinking and creativity.

As mentioned before, many universities either lack published AI policies or only provide general guidelines that omit task-specific contexts (debugging code or interpreting lab results etc.). Our unified policy addresses these

gaps. Through our interface, users can easily locate policies and “dos and don’ts” for specific tasks, clarifying where AI can be appropriately integrated to enhance productivity without undermining learning.

Furthermore, our unified policy includes specific guidelines for educators to follow when creating course

material or curriculum, including tasks such as creating assessments that AI tools cannot easily complete. These guidelines were refined in collaboration with Dr Hussain Ahmad, whose experience as an educator complemented our perspective as students.

Finally, the unified policy also serves as a call to action for institutions that have yet to publish comprehensive or clear AI usage guidelines. By promoting clarity, ethical use, and collaboration rather than restriction, our work supports a smoother, more responsible integration of AI into education (and learning) as the technology continues to advance.

Limitations

Our university's GenAI policy project faced three main limitations that compromised the quality and reliability of our work. These shortcomings include a lack of international university policies that would have broadened our perspectives, inaccessible GenAI policies restricting our database and research, and a strict timeframe forcing us to rush the latter half of our project. Most of these limitations could have been avoided with better planning; however, we had to make do when dealing with unavailable resources.

The focus of this project was universities in Australasia (Australia and New Zealand). The scope of our research covers a large area with many universities but is still contained in a small zone of the wider world. There are hundreds of universities and similar tertiary institutions from all around the world, each with different interpretations of how AI should be used appropriately and ethically in study, research, and academic support.

Our analyses examine each universities' scope, clarity, and implementation. We noted common trends, strengths, and any gaps or weaknesses in each universities' policy. For instance, students were often not allowed to prompt AI to generate answers to questions, and course coordinators were required to outline ethical AI use guidelines for their course and/or assignments. Based on our analyses, we developed our own GenAI use policy to unify the

varying scopes across universities. However, our narrow list of sources limits the effectiveness of the unified policy and still has patterns and trends found in many of the universities we analysed.

Having different international understandings of AI would have advanced our project and allowed us to compare the scope and effectiveness of Australasian universities to broadening perspectives influenced by different cultures. The quality of our analyses suffers because we have evaluated sources from the same or similar cultural backgrounds and societal expectations of tertiary education.

The first major task we had to complete to do anything in our project was find the GenAI policies for each university and summarise their rules on what is permitted and not permitted with AI. With this database, we could continue to categorise them into two trees for both parties, analyse the data and insights, and create our own unified policy.

Creating this database was very simple and routine: find the university's AI use policy online and summarise it. However, doing so assumes that these policies are publicly available online. There were some policies that we couldn't source because the only way to access them was to log in to a student or staff portal.

None of us were enrolled at those outlying universities, so we decided to omit those policies from our sources. This did not majorly impact the quality of our work; we still found plenty of sources and material to categorise and analyse. Nevertheless, we are missing some sources that may have had useful or unique information to analyse and possibly incorporate into our unifying policy.

Most of the time working on this project over the semester was spent researching. Following the 28 Australasian universities from the ACDICT members list, we had to find their GenAI use policies online and summarise them. Next, we had to create and workshop a taxonomy to organise each policy's rules. Two trees, students and educators, would branch out into more detailed levels for various use cases of

AI, and each university's rules would be categorised into the appropriate taxonomy.

All this research and taxonomy took a great deal of time to complete. More than half of the semester was dedicated to these heavy and foundational tasks. Later, we had to analyse our organised university policies for strengths and trends and then create our own unified policy that could be used by all universities.

Later in the semester, we were running out of time. We were rushed in the final steps of the project, and this hindered the quality of the work. While we did manage to analyse and create a policy that was presentable, with more time we could have received feedback on it, iterated on it, and possibly even had it reviewed by an appropriate university official.

Our group project had limitations throughout its development that affected the research and the quality of the product. Our analyses and unified policy didn't cover international sources, thus our evaluations were based on the same culture and expectations of university education. The database of summarised AI policies was only sourced from online university websites, some of which were unavailable or blocked from public use; while this didn't majorly affect subsequent work, there's no way of knowing what we have missed. This could be changed by contacting them for this information. Most of the semester was spent on researching and workshopping policy taxonomy, making the later analysis and unified policy rushed, impacting their overall quality. These limitations could have been avoided with better planning and more time to refine the quality of the analysis, the unified policy, and the details of the research and scope of the source.

Conclusion

At the beginning of the semester, we set out to build a common standard for the ethical use of generative AI at universities, synthesised from the collective policies of top Australasian institutions. In order to explain our framework to educators and students, we also set out to develop an intuitive web app. During the course of the semester, we achieved these goals: We examined the policies of Australasian universities, breaking down and summarising them such that they could be compared. We took these and developed policy categories to understand the fundamental areas that needed to be addressed. We created a comprehensive unified policy and a web app to explain it, complete with diagrams and examples to boost understanding. To further our project would require greater access to universities; our unified policy was developed on the basis of publicly available information, but insight into the real-world effectiveness of various policy approaches would require university

records and careful interpretation. Perhaps the unified policy framework could be trialled and refined if it gained more acceptance. From there, there could be a real path to wide adoption.
